

User is invited to a concert, but since he's deaf, he's worried he's not gonna enjoy the show. His friend tells him that this is gonna be a deaf-friendly show.

The show starts, and the crowd is enjoying the music. However, our user can't hear anything and asks his friend what's going on. The friend urges him to wait for a new feature.

The musician turns on the lights feature (wires), so that the audience can enjoy the visual effects linked to the piano notes he is playing.

The user is able to perceive the melody through the colors of the lights shown. He is very happy he's able to "listen" to the music. His friend is happy as well.

After the show ends, the user approaches the piano player to say thank you, and share how meaningful this experience was to him. The musician invites him to try the piano himself.

The user tries the ocular harpsichord and he is very happy to finally "feel" what each piano key generates: all together: a melody.

Our user finds online information about the ocular harpsichord. This is exactly combining 2 of the topics he's most interested in: accessibility and music.

After researching the technical specs of the ocular harpsichord, our user realizes this is trickier than what he initially thought. He decides to try different approaches to make it work.

The first test he runs is on a traditional analog piano. After several attempts, he realizes connecting linking the keynotes to the light colors is very difficult. Our user feels frustration.

After thinking a lot, our user comes up with a new idea: "what if I use an electronic keyboard, and create a sw that controls the light tones?" He starts developing the digital version right away.

Once the program is developed, our user realized that he can create a similar version with an actual ^{piano} keyboard and smart bulbs. This would be a closer prototype to the original harpsichord.

The user showcases his new tool in a design exhibition and gathers some useful feedback for a new iteration of the digital ocular harpsichord.
